Abstract: Remote sensing hue anomaly is an important indication for remote sensing mineralization information identification and ore - finding. Ratiom enhancement and principal component analyses are main ways for extracting alteration information. However, there is no unified standard how to identify and classify anomaly hues of multi - spectral remote sensing data. Based on image enhancement, characteristic vector selection, characteristic vector assemble analysis and anomaly hue distributing rules, model dictionary in the studied area is established and alteration information theory is put forward. Quantitative inverse of anomaly hues is conducted based on alteration information. Remarkable prediction results are got in the Xiaoxinancha gold deposit.

Key words: alteration information field, model identification dictionary, anomaly hue, quantitative inversion
